**Experiment / assignment / tutorial No.**

**Grade: AA / AB / BB / BC / CC / CD /DD**

**Signature of the Staff In-charge with date**

**TITLE: Polymorphism and Abstract Class**

**AIM:**

Write a program that defines an abstract class called Vehicle containing an abstract method speed (). Derive from it two classes - FourWheeler and TwoWheeler. Create objects of derived classes and call the speed () method using these objects, passing to it the name of vehicle and speed of vehicle. In the speed () method print the vehicle name and the speed of vehicle to which speed () belongs.

---

**Expected OUTCOME of Experiment:**

CO1: Use basic data structures in Python

CO2: Use different Decision Making statements and Functions in Python.

CO3: Apply Object oriented programming concepts in Python

---

**Resource Needed: Python IDE**

---

**Theory:**

**Polymorphism:**

Polymorphism is taken from the Greek words Poly (many) and morphism (forms). It means that the same function name can be used for different types. This makes programming more intuitive and easier.

**Polymorphism in Python:**

A child class inherits all the methods from the parent class. However, in some situations, the method inherited from the parent class doesn't quite fit into the child class. In such cases, you will have to re-implement method in the child class.

There are different methods to use polymorphism in Python. You can use different function, class methods or objects to define polymorphism.

**Polymorphism with Function and Objects:**

You can create a function that can take any object, allowing for polymorphism.

**Example:**

## K. J. Somaiya College of Engineering, Mumbai-77

(A Constituent College of Somaiya Vidyavihar University)

Create a function called “func()” which will take an object which we will name “obj”. and let give the function something to do that uses the ‘obj’ object which is passed to it. Now, call the methods type() and color(), each of which is defined in the two classes ‘Tomato’ and ‘Apple’ by creating instances of both the ‘Tomato’ and ‘Apple’ classes if they do not exist:

```
class Tomato():
    def type(self):
        print("Vegetable")
    def color(self):
        print("Red")
class Apple():
    def type(self):
        print("Fruit")
    def color(self):
        print("Red")
```

```
def func(obj):
    obj.type()
    obj.color()
```

```
obj_tomato = Tomato()
obj_apple = Apple()
func(obj_tomato)
func(obj_apple)
```

### Output:

```
Vegetable
Red
Fruit
Red
```

### Polymorphism with Class Methods:

Python uses two different class types in the same way. Here, you have to create a for loop that iterates through a tuple of objects. Next, you have to call the methods without being concerned about which class type each object is. We assume that these methods actually exist in each class

### Example:

## K. J. Somaiya College of Engineering, Mumbai-77

(A Constituent College of Somaiya Vidyavihar University)

```
class India():
    def capital(self):
        print("New Delhi")

    def language(self):
        print("Hindi and English")

class USA():
    def capital(self):
        print("Washington, D.C.")

    def language(self):
        print("English")

obj_ind = India()
obj_usa = USA()
for country in (obj_ind, obj_usa):
    country.capital()
    country.language()
```

### Output:

```
New Delhi
Hindi and English
Washington, D.C.
English
```

### Polymorphism with Inheritance:

Polymorphism in python defines methods in the child class that have the same name as the methods in the parent class. In inheritance, the child class inherits the methods from the parent class. Also, it is possible to modify a method in a child class that it has inherited from the parent class.

This is mostly used in cases where the method inherited from the parent class doesn't fit the child class. This process of re-implementing a method in the child class is known as Method Overriding.

### Example:

```
class Bird:
    def intro(self):
        print("There are different types of birds")

    def flight(self):
        print("Most of the birds can fly but some cannot")

class parrot(Bird):
    def flight(self):
        print("Parrots can fly")

class penguin(Bird):
    def flight(self):
        print("Penguins do not fly")

obj_bird = Bird()
obj_parr = parrot()
obj_peng = penguin()

obj_bird.intro()
obj_bird.flight()

obj_parr.intro()
obj_parr.flight()

obj_peng.intro()
obj_peng.flight()
```

### Output:

```
There are different types of birds
Most of the birds can fly but some cannot
There are different types of bird
Parrots can fly
There are many types of birds
Penguins do not fly
```

### **Abstract Class:**

Abstract Class is concept of object-oriented programming based on DRY (Don't Repeat Yourself) principle. In a large project, code duplication is approximately equal to bug reuse and one developer is impossible to remember all classes' details. Therefore, it's very helpful to use an abstract class to define a common interface for different implementations.

An abstract class has some features, as follows:-

- An abstract class doesn't contain all of the method implementations required to work completely, which means it contains one or more abstract methods. An abstract method is a method that just has a declaration but does not have a detail implementation.
- An abstract class cannot be instantiated. It just provides an interface for subclasses to avoid code duplication. It makes no sense to instantiate an abstract class.
- A derived subclass must implement the abstract methods to create a concrete class that fits the interface defined by the abstract class. Therefore it cannot be instantiated unless all of its abstract methods are overridden.

### **Define Abstract Class in Python:**

Python comes with a module called abc which provides methods for abstract class.

Define a class as an abstract class by abc.ABC and define a method as an abstract method by abc.abstractmethod. ABC is the abbreviation of abstract base class.

### **Example:**

```
from abc import ABC, abstractmethod
```

```
class Animal(ABC):
    @abstractmethod
    def move(self):
        pass
a = Animal()           # TypeError: Can't instantiate abstract class Animal with abstract methods
                        move
```

```
class Animal():
    @abstractmethod
    def move(self):
        pass
a = Animal()           # No errors
```

### **Invoke Methods from Abstract Classes:**

An abstract method is not needed to be “totally abstract” in Python. We can define some content in an abstract method and use super() to invoke it in subclasses.

**K. J. Somaiya College of Engineering, Mumbai-77**

(A Constituent College of Somaiya Vidyavihar University)

**Example:**

```
from abc import ABC, abstractmethod
```

```
class Animal(ABC):  
    @abstractmethod  
    def move(self):  
        print('Animal moves')
```

```
class Cat(Animal):  
    def move(self):  
        super().move()  
        print('Cat moves')
```

```
c = Cat()  
c.move()
```

**Output:**

Animal moves  
Cat moves

**Problem Definition:**

1. For given program find output

Sr.No	Program	Output
-------	---------	--------

## K. J. Somaiya College of Engineering, Mumbai-77

(A Constituent College of Somaiya Vidyavihar University)

1	<pre>class Bank:     def getroi(self):         return 10  class SBI:     def getroi(self):         return 7  class ICICI:     def getroi(self):         return 8  b1=Bank() b2=SBI() b3=ICICI() print("Bank rate of interest:",b1.getroi()) print("SBI rate of interest:",b2.getroi()) print("ICICI rate of interest:",b3.getroi())</pre>	Bank rate of interest: 10 SBI rate of interest: 7 ICICI rate of interest: 8
2.	<pre>from abc import ABC, abstractmethod class Employee(ABC):     @abstractmethod     def calculate_salary(self,sal):         pass  class Developer(Employee):     def calculate_salary(self,sal):         finalsalary=sal*1.10         return finalsalary  emp_1=Developer() print(emp_1.calculate_salary(10000))</pre>	11000.0

1. Write a program that defines an abstract class called Vehicle containing an abstract method speed (). Derive from it two classes - FourWheeler and TwoWheeler. Create objects of derived classes and call the speed () method using these objects, passing to it the name of vehicle and speed of vehicle. In the speed () method print the vehicle name and the speed of vehicle to which speed () belongs.

**Implementation details:**

```
from abc import ABC, abstractmethod
class vehical(ABC):
    def __init__(self,name,_speed):
        self.name=name
        self._speed=_speed

    @abstractmethod
    def speed(self):
        pass
class twowheeler(vehical):
    def speed(self):
        print(self.name)
        print(self._speed)

class fourwheeler(vehical):
    def speed(self):
        print(self.name)
        print(self._speed)

a=twowheeler("honda",100)
a.speed()
b=fourwheeler("nano",50)
b.speed()
```

**Output(s):**

honda  
100  
nano  
50

**Conclusion:**

**Thus we have successfully understood how abstract classes work in python. We used the abc module for this purpose. Abstraction is a special feature of OOP. Abstraction allows us to use polymorphism.**

**Post Lab Questions**

**1. What will be the output of the following Python code?**

```
class A:
    def __init__(self):
        self.multiply(15)
        print(self.i)

    def multiply(self, i):
        self.i = 4 * i;

class B(A):
    def __init__(self):
        super().__init__()

    def multiply(self, i):
        self.i = 2 * i;

obj = B()
```

(A Constituent College of Somaiya Vidyavihar University)

**Options**

- a) 15
- b) 60
- c) An exception is thrown
- d) 30

**Second method will be implemented. (Method of b)**

2. A class in which one or more methods are only implemented to raise an exception is called an abstract class.

- a) True
- b) False

- b) False
